# Deriving Transition Probabilities for Decision Models

Risha Gidwani, DrPH March 2016

# Transition probabilities drive the decision model

 Probability of moving from one health state to another (state-transition model)

 Probability of experiencing an event (discrete-event simulations)

#### Goal

 (Transition) probabilities are the engine to a decision model

 You will often derive these probabilities from literature-based inputs

Learn when and how you can do this

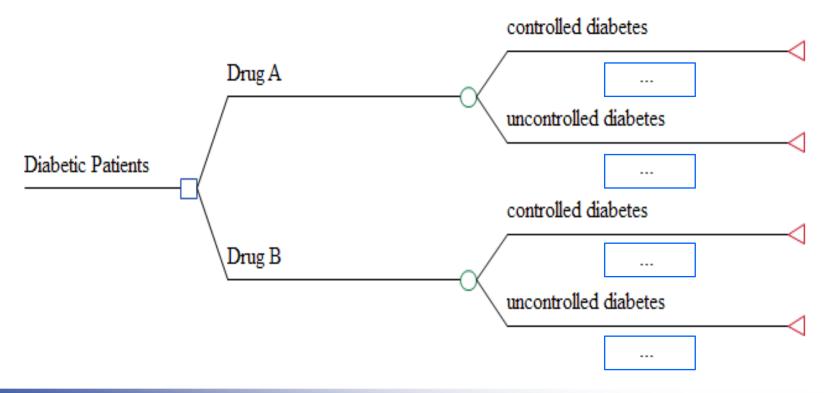

#### Acknowledgements

Rita Popat, PhD

Clinical Associate Professor
Division of Epidemiology
Dept. of Health Research and Policy
Stanford University School of Medicine

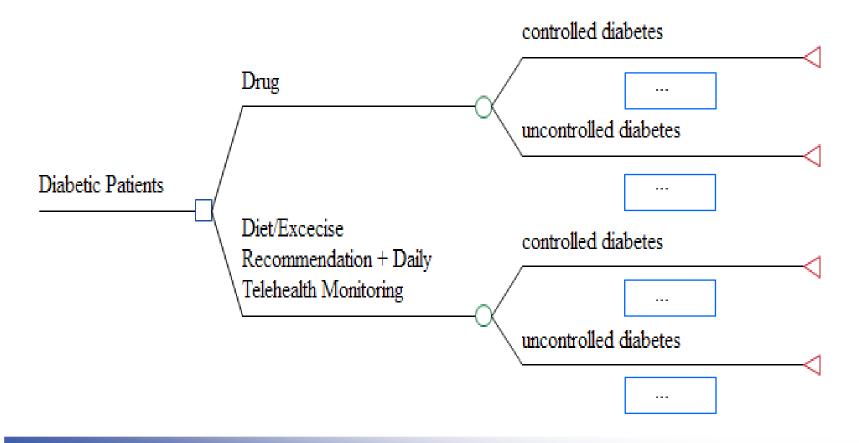

#### Probabilities in a Decision Model

 You have a cost-effective model, now you need inputs for your transition probabilities

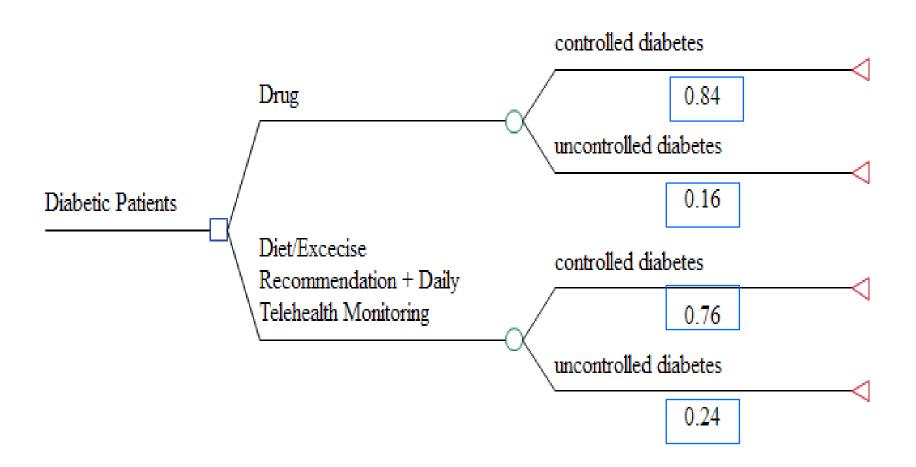

#### Probabilities in a Decision Model

■ Does not have to be 2 drugs – can be any strategies

#### **Probability Inputs**

#### Ways to derive model inputs

- Obtain existing data from a single study
- Synthesizing existing data from multiple studies
  - Meta-Analysis
  - Mixed Treatment Comparisons
  - Meta-Regression

## USING EXISTING DATA FROM A SINGLE STUDY

#### Plucking inputs from the literature

If you are extremely lucky, you will read a journal article that will have exactly the type of information you need.

- The vast majority of people are not extremely lucky.

Modify existing literature to derive your model inputs

#### Using inputs from the literature

- Many types of inputs are available from the literature
  - Probability (risk)
  - Rate (mortality)
  - Relative Risk
  - Odds Ratio
  - Risk Difference
  - Mean
  - Median
- We need data in the form of probabilities for use in a model

#### What do these inputs mean?

Statistic	Evaluates	Range
Probability/Risk (aka Incidence Proportion)	# of events that occurred in a time period # of people followed for that time period	0-1
Rate	# of events that occurred in a time period  Total time period experienced by all subjects followed	0 to ∞
Relative Risk (aka Risk Ratio)	k (aka Risk Probability of outcome in exposed Probability of outcome in unexposed	
Odds	Probability of outcome  1 — Probability of outcome	0 to ∞
Odds Ratio	Ids Ratio Odds of outcome in exposed Odds of outcome in unexposed	
Risk Difference Difference in risk (probability) of event amongst exposed and unexposed		-1 to 1
Survival Curve	Curve Point =  # of people who are alive at time t   being alive at time t – 1	
Mean	Sum of all observations  Total # of observations	- ∞ to ∞

#### Comparative, Non-Comparative Data

Statistic	Evaluates	Type of Data	
Probability/Risk	# of events that occurred in a time period # of people followed for that time period	Non-Comparative	
Rate	# of events  Total time period experienced by all subjects followed	Non-Comparative	
Odds	Probability of outcome  1 — Probability of outcome	Non-Comparative	
Odds Ratio	Odds of outcome in exposed Odds of outcome in unexposed	Comparative	nsform to
Relative Risk (aka Risk Ratio)	Probability of outcome in exposed Probability of outcome in unexposed	Comparative	n-Comparative ta
Risk Difference	Difference in risk (probability) of event amongst exposed and unexposed	Comparative	
Survival Curve	Point = # of people who are alive at time t   being alive at time t - 1	Non-Comparative	
Mean	Sum of all observations Total # of observations	Non-Comparative	

#### Inputs for a decision model require non-comparative data:

- Ex. 1) Probability of controlled diabetes with Drug A as the first input
  - 2) Probability of controlled diabetes with Drug B as the second input

# Using probabilities from the literature

 Literature-based probability may not exist for your time frame of interest

 Transform this probability to a time frame relevant for your model

#### Example:

- 6-month probability of controlled diabetes is reported in the literature
- Your model has a 3-month cycle length
- You need a 3-month probability

# Probabilities cannot be manipulated easily

Cannot multiply or divide probabilities

100% probability at 5 years does NOT mean a
 20% probability at 1 year

30% probability at 1 year does NOT mean a 120% probability at 4 years

#### **Probabilities and Rates**

- Rates can be mathematically manipulated -- added, multiplied, etc.
  - Probabilities cannot

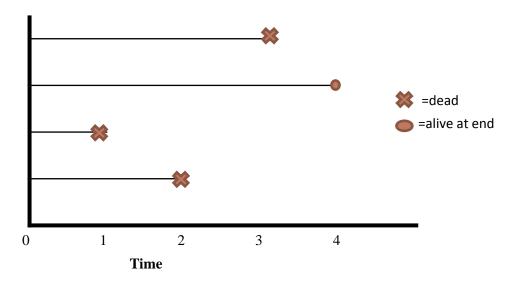

To change time frame of probability:

**Probability** → **Rate** → **Probability** 

Note: Assumes the event occurs at a constant rate over a particular time period

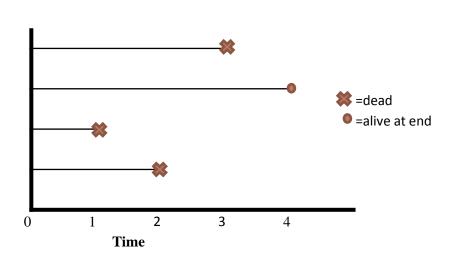

#### Rates versus probabilities

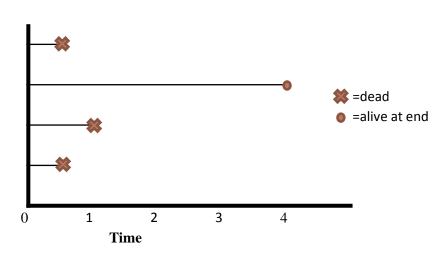

• In a rate, you care <u>when</u> the event happened – this changes the rate (but not the probability)

- The rate of death is 3/(3+4+1+2) = 3/10:
  - 3 per 10 person-years, 0.3 per person-year
- The probability of death is 3/4:
  - 75%

#### Rates versus probabilities, 2

### Rate of death = 0.3 per person-year 3/(3+4+1+2) = 3/10

Probability of death = 75%

$$= \frac{3}{4}$$

Rate of death 
$$= 0.5$$
 per person-year

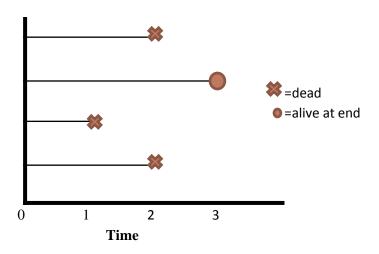

$$3/(0.5+4+1+0.5) = 3/6$$

Probability of death = 75%

$$= \frac{3}{4}$$

#### **Example-Question**

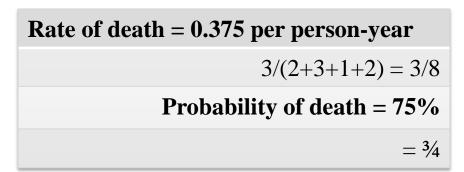

Calculate the <u>rate of death</u> and the <u>probability of death</u> from the following data:

#### **Example- Answer**

Calculate the <u>rate of death</u> and the <u>probability of death</u> from the following data:

#### **Probability-Rate Conversions**

Probability to rate

Rate = 
$$\frac{-\ln(1-p)}{t}$$

Rate to probability

Probability = 
$$1 - exp^{(-rt)}$$

p = probability
t = time
r = rate

#### Example

- 3-year probability of controlled diabetes is 60%
  - What is the 1-year probability of controlled diabetes?
- Assume incidence rate is constant over 3 years:

- Rate = 
$$\frac{-\ln(1-p)}{t}$$

$$- = \frac{-\ln(1-0.6)}{3} = 0.3054$$

- Probability = 
$$1 - exp^{(-rt)}$$
  
=  $1 - e^{(-0.3054 \times 1)} = 0.2632$   
=  $26\%$ 

#### Question

- 30% of people have controlled diabetes at 5 years.
- What is the 1-year probability of controlled diabetes?
  - Probability to rate

Probability = 
$$1 - exp^{(-rt)}$$

Rate to probability

Rate = 
$$\frac{-\ln(1-p)}{t}$$

```
p = \text{probability}

t = \text{time}

t = \text{rate}
```

#### Answer

- A 5-year probability of 30% is a 1-year probability of **6.89%**.
- Equations:

Rate: 
$$\frac{-\ln(1-0.30)}{5} = 0.0713$$

Probability:  $1 - e^{(-0.0713 \times 1)} = 6.89\%$ 

### Converting to Probabilities?

	Statistic	Convert to probability?
✓	Probability/Risk (aka Incidence Proportion)	Yes (it is already one, but use rates to convert the time period to which they apply)
✓	Rate	Yes
	Relative Risk (aka Risk Ratio)	
	Odds	
	Odds Ratio	
	Risk Difference (x-y=z)	
	Survival Curve	
	Mean	

#### In the beginning...

there were 2 by 2 tables:

	Outcome – Yes	Outcome - No
Exposed	a	b
Unexposed	С	d

Probability of outcome in exposed =  $\frac{a}{a+b}$ 

*Odds Ratio*: 
$$\frac{\frac{a}{b}}{\frac{c}{d}} = \frac{a}{b} \times \frac{d}{c} = \frac{ad}{bc}$$

Relative Risk:  $\frac{\left(\frac{a}{a+b}\right)}{\left(\frac{c}{c+d}\right)}$ 

#### In the beginning...

there were 2 by 2 tables:

	Controlled Diabetes	Uncontrolled Diabetes
Drug A	a	b
Placebo	С	d

Probability of controlled diabetes with Drug  $A = \frac{a}{a+b}$ 

*Odds Ratio*: 
$$\frac{\frac{a}{b}}{\frac{c}{d}} = \frac{a}{b} \times \frac{d}{c} = \frac{ad}{bc}$$

Relative Risk:  $\frac{(\frac{a}{a+b})}{(\frac{c}{c+d})}$ 

#### OR versus RR

Statistic	Evaluates	
Relative Risk (aka Risk Ratio)	Probability of outcome in exposed	
	Probability of outcome in unexposed	
Odds Ratio	Odds of outcome in exposed	
	Odds of outcome in unexposed	
Odds	Probability of outcome	
	1 — Probability of outcome	

- RR is easier to interpret than OR
- But, the OR has better statistical properties
  - OR of harm is inverse of OR of benefit
  - RR of harm is not the inverse of RR of benefit
- Much data in the literature is reported as OR

#### Probability from RR

$$RR = \frac{probability\ in\ exposed}{probability\ in\ unexposed}$$

This requires that you are able to find the probability of unexposed in the journal article

#### Probability from RR, example

#### Example:

- -RR = 2.37
- Probability in unexposed = 0.17
- Probability in exposed = 2.37 \* 0.17

$$= 0.403$$

$$=40.3\%$$

over the entire study period

#### Probability from RR, caveat

- If the RR is the result of a regression, it has been *adjusted* for covariates
- But, the probability in the unexposed will be unadjusted

```
Prob (exposed) = RR * prob(unexposed_unadjusted)

Prob (exposed) = prob(exposed_adjusted) * prob (unexposed_unadjusted)

prob(unexposed_adjusted)
```

Therefore, your derived probability estimate will have some bias
 so make sure you vary this extensively in sensitivity analyses!!

#### RR are nice, but...

 OR are more likely to be reported in the literature than RR

#### Probability from OR

■ IF the outcome is rare ( $\leq 10\%$ ), then you can assume that the OR approximates the RR

If the outcome is not rare → advanced topic, do not proceed without consulting a statistician

#### **OR versus RR**

The relationship between risk ratio (RR) and odds ratio by incidence of the outcome.

OR is a good measure of RR when the outcome is rare

### Calculating Probability from OR

- If outcome is rare, assume OR approximates RR
- Prob (exposed) =  $\aleph$  \* prob(unexposed)

#### Example:

$$OR = 1.57$$

Prob. of outcome in unexposed: 8% → rare

prob (exposed) = 1.57 \* 0.08 = 12.56%

	Outcome - Yes	Outcome - No
Exposed	12	88
Unexposed	8	92

### **Prob**<sub>Unexposed</sub>

- Whether you can assume the OR approximates RR depends on the probability of outcome in the unexposed
- Should be available in the paper
- If it is not try going to the literature to find this value for a similar group of patients

## **Probability from Odds**

$$odds = \frac{probability}{1 - probability}$$
  $probability = \frac{odds}{1 + odds}$ 

Odds of 1/7 =

Probability of 0.125

$$Probability = \frac{1/7}{8/7} = \frac{0.143}{1.143} = 0.125$$

## Probability from Stata, directly

- "Margins" command
- logistic y i.x
- margins i.x

Will give you predicted probabilities of x, given y = 1

# Converting to Probabilities?

	Statistic	Convert to probability?
✓	Probability/Risk (aka Incidence Proportion)	n/a (use rates to convert the time period to which they apply)
<b>✓</b>	Rate	Yes
✓	Odds	Yes
✓	Odds Ratio	Yes, if the outcome is rare ( $\leq 10\%$ ) & you have probability in unexposed
<b>✓</b>	Relative Risk (aka Risk Ratio)	Yes, if you have the probability in the unexposed
	Risk Difference (x-y=z)	
	Survival Curve	
	Mean	

#### Risk Difference

- Risk in one group minus risk in the other
- Risk = probability

■ Prob<sub>Drug A</sub>- Prob<sub>placebo</sub> = Risk Difference

 $\mathbf{0.84} - 0.17 = 0.67$ 

## Risk Difference, con't

- Prob<sub>treatment</sub>- Prob<sub>control</sub> = Risk Difference
- If the article gives you Risk Difference, it will often give you Prob<sub>treatment</sub> or Prob<sub>control</sub>
- If article gives you Prob<sub>treatment</sub>, use that directly
- If article Prob<sub>control</sub>, use that and the Risk Difference to derive Prob<sub>treatment</sub>

# Converting to Probabilities?

	Statistic	Convert to probability?
<b>✓</b>	Probability/Risk (aka Incidence Proportion)	Yes (it is already one, but use rates to convert the time period to which they apply)
<b>✓</b>	Rate	Yes
✓	Odds	Yes
<b>✓</b>	Odds Ratio	Yes, if the outcome is rare ( $\leq 10\%$ ) & you have probability in the unexposed
✓	Relative Risk (aka Risk Ratio)	Yes, if you have the probability in the unexposed
✓	Risk Difference (x-y=z)	Yes, if the paper reports x or y in addition to z
	Survival Curve	
	Mean	

## Survival data and probabilities

 All previous probabilities were assumed to be constant throughout the model (Don't have to be, but can be)

 Survival should NOT be assumed to be constant over time

 So, you will have multiple probabilities for "death" in your model – one for each time period of interest.

#### Sources of survival data

- All-cause mortality (CDC)
  - age- and sex-adjusted <u>rates</u>

- Disease-specific/Treatment-specific
   literature
  - Probability of death at t
  - Survival Curves

#### Reported survival rates

Table 3. Number of deaths and death rates, by age, race, and sex: United States, 2010—Con.

[Rates per 100,000 population in specified group. Rates are based on populations enumerated in the 2010 census as of April 1; see Technical Notes. Data for specified races other than white and black should be interpreted with securior because of inconsistencies between reporting race on death certificates and on censuses and surveys; see Technical Notes]

		All races			White <sup>1</sup>			Black <sup>1</sup>		American	Indian or Alask	ka Native <sup>1,2</sup>	Asian o	r Pacific Isl	ander <sup>1,3</sup>
Age (years)	Both sexes	Male	Female	Both sexes	Male	Female	Both sexes	Male	Female	Both sexes	Male	Female	Both sexes	Male	Female
								Rate

10	85	.1429
11	86	.1429
	•	

#### Disease-Specific Survival Data

- Kaplan-Meier Curve
  - Unadjusted
    - RCT data

- Cox Proportional Hazards Curve
  - Adjusted
    - observational data

#### Survival Data from Curves

# Deriving probability from mean (continuous distribution)

- 1) Need a validated way to generate a binary variable from a continuous distribution -- threshold
  - HbA1c < 7 = controlled diabetes

- 2) Need an estimate of variation around the mean (SD, variance) or median (IQR, range)
  - Involve a statistician!

# Converting to Probabilities?

	Outcome	Convert to probability?
✓	Probability/Risk (aka Incidence Proportion)	Yes (it is already one, but use rates to convert the time period to which they apply)
✓	Rate	Yes
✓	Odds	Yes
<b>√</b>	Odds Ratio	Yes, if the outcome is rare ( $\leq 10\%$ ) & you have prob. in unexposed
<b>✓</b>	Relative Risk (aka Risk Ratio)	Yes, if you have the probability in the unexposed
✓	Risk Difference (x-y= z)	Most likely, because they will give you x or y in addition to z
✓	Survival Curve	Yes, but remember they are conditional and may change with each time period
✓	Mean	Yes, if you have estimate of variation

#### **Estimates of variation**

 You will still need to derive estimates of variation around your derived point estimate of probability

Necessary for sensitivity analyses

Advanced Topic

#### Quality of the literature

THE QUALITY OF THE LITERATURE MATTERS GREATLY!!

- Preferences for literature-based inputs:
  - 1. These two treatments studied in a head-to-head RCT
  - 2. a) Drug compared to placebo in RCT, and
    - b) Diet/Exercise/Telehealth compared to placebo in another RCT, and
    - c) these two RCTs enrolled similar patients

## Summary

- Need to transform reported data to probabilities for use in a decision model
  - Easiest: Rate, OR if outcome <10%, RR, survival data
  - More difficult, but possible: Continuous data with estimate of variation
  - Advanced topics: OR when outcome > 10%, mean difference, standardized mean difference
- Probs. apply to particular length of time
  - To change the length of time to which a probability applies:
    - Probability → rate → probability
